1 What is H2O?

H2O is fast, scalable, open-source machine learning and deep learning for smarter applications. With H2O, enterprises like PayPal, Nielsen Catalina, Cisco, and others can use all their data without sampling to get accurate predictions faster. Advanced algorithms such as deep learning, boosting, and bagging ensembles are built-in to help application designers create smarter applications through elegant APIs. Some of our initial customers have built powerful domain-specific predictive engines for recommendations, customer churn, propensity to buy, dynamic pricing, and fraud detection for the insurance, healthcare, telecommunications, ad tech, retail, and payment systems industries.

Using in-memory compression, H2O handles billions of data rows in-memory, even with a small cluster. To make it easier for non-engineers to create complete analytic workflows, H2O’s platform includes interfaces for R, Python, Scala, Java, JSON, and CoffeeScript/JavaScript, as well as a built-in web interface, Flow. H2O is designed to run in standalone mode, on Hadoop, or within a Spark Cluster, and typically deploys within minutes.

H2O includes many common machine learning algorithms, such as generalized linear modeling (linear regression, logistic regression, etc.), Naïve Bayes, principal components analysis, k-means clustering, and others. H2O also implements best-in-class algorithms at scale, such as distributed random forest, gradient boosting, and deep learning. Customers can build thousands of models and compare the results to get the best predictions.

H2O is nurturing a grassroots movement of physicists, mathematicians, and computer scientists to herald the new wave of discovery with data science by collaborating closely with academic researchers and industrial data scientists. Stanford university giants Stephen Boyd, Trevor Hastie, Rob Tibshirani advise the H2O team on building scalable machine learning algorithms. With hundreds of meetups over the past three years, H2O has become a word-of-mouth phenomenon, growing amongst the data community by a hundred-fold, and is now used by 30,000+ users and is deployed using R, Python, Hadoop, and Spark in 2000+ corporations.

Try it out

- Download H2O directly at http://h2o.ai/download.
- Install H2O’s R package from CRAN at https://cran.r-project.org/web/packages/h2o/.
- Install the Python package from PyPI at https://pypi.python.org/pypi/h2o/.

2 Sparkling Water Introduction

Sparkling Water allows users to combine the fast, scalable machine learning algorithms of H2O with the capabilities of Spark. With Sparkling Water, users can drive computation from Scala, R, or Python and use the H2O Flow UI, providing an ideal machine learning platform for application developers.

Spark is an elegant and powerful general-purpose, open-source, in-memory platform with tremendous momentum. H2O is an in-memory application for machine learning that is reshaping how people apply math and predictive analytics to their business problems.

Integrating these two open-source environments provides a seamless experience for users who want to make a query using Spark SQL, feed the results into H2O to build a model and make predictions, and then use the results again in Spark. For any given problem, better interoperability between tools provides a better experience.

For additional examples, please visit the Sparkling Water GitHub repository at https://github.com/h2oai/sparkling-water/tree/master/examples.

2.1 Typical Use Cases

Sparkling Water excels in leveraging existing Spark-based workflows needed to call advanced machine learning algorithms. We identified three the most common use-cases which are described below.

2.1.1 Model Building

A typical example involves multiple data transformations with help of Spark API, where a final form of data is transformed into H2O frame and passed to
an H2O algorithm. The constructed model estimates different metrics based on
the testing data or gives a prediction that can be used in the rest of the data
pipeline (see Figure 1).

Figure 1: Sparkling Water extends existing Spark data pipeline with advanced
machine learning algorithms.

2.1.2 Data Munging

Another use-case includes Sparkling Water as a provider of ad-hoc data trans-
formations. Figure 2 shows a data pipeline benefiting from H2O’s parallel data
load and parse capabilities, while Spark API is used as another provider of data
transformations. Furthermore, H2O can be used as in-place data transformer.

2.1.3 Stream Processing

The last use-case depicted on Figure 3 introduces two data pipelines. The first
one, called an off-line training pipeline, is invoked regularly (e.g., every hour or
every day), utilizes Spark as well as H2O API and provides an H2O model as
output. The H2O API allows the model to be exported in a source code form.
The second one processes streaming data (with help of Spark Streaming or
Storm) and utilizes the model trained in the first pipeline to score the incoming
data. Since the model is exported as a code, the streaming pipeline can be
lightweight and independent on H2O or Sparkling Water infrastructure.
2.2 Features

Sparkling Water provides transparent integration for the H2O engine and its machine learning algorithms into the Spark platform, enabling:

- Use of H2O algorithms in Spark workflow
- Transformation between H2O and Spark data structures
- Use of Spark RDDs and DataFrames as input for H2O algorithms
- Use of H2OFrames as input for MLlib algorithms
- Transparent execution of Sparkling Water applications on top of Spark

2.3 Supported Data Sources

Currently, Sparkling Water can use the following data source types:

- Standard Resilient Distributed Dataset (RDD) API for loading data and transforming it into H2OFrames
- H2O API for loading data directly into H2OFrame from file(s) stored on:
  - local filesystems
  - HDFS
  - S3
Figure 3: Sparkling Water used as an off-line model producer feeding models into a stream-based data pipeline.

- HTTP/HTTPS

For more details, please refer to the H2O documentation at http://docs.h2o.ai.

2.4 Supported Data Formats

Sparkling Water can read data stored in the following formats:

- CSV
- SVMLight
- ARFF

For more details, please refer to the H2O documentation at http://docs.h2o.ai.

2.5 Supported Spark Execution Environments

Sparkling Water can run on top of Spark in the following ways:

- as a local cluster (where the master node is local, local[*], or local-cluster[...])
• as a standalone cluster\textsuperscript{1}
• in a YARN environment\textsuperscript{2}

\textsuperscript{1}Refer to the Spark standalone documentation http://spark.apache.org/docs/latest/spark-standalone.html
\textsuperscript{2}Refer to the Spark YARN documentation http://spark.apache.org/docs/latest/running-on-yarn.html
3 Design

Sparkling Water is designed to be executed as a regular Spark application. It provides a way to initialize H2O services on each node in the Spark cluster and access data stored in data structures of Spark and H2O.

Since Sparkling Water is primarily designed as Spark application, it is launched inside a Spark executor created after submitting the application. At this point, H2O starts services, including distributed key-value (K/V) store and memory manager, and orchestrates them into a cloud. The topology of the created cloud replicates the topology of the underlying Spark cluster.

![Sparkling Water design](image)

Figure 4: Sparkling Water design depicting deployment of the Sparkling Water application to the standalone Spark cluster.

3.1 Data Sharing between Spark and H2O

Sparkling Water enables transformation between different types of RDDs and H2O’s H2OFrame, and vice versa.

When converting from an H2OFrame to an RDD, a wrapper is created around the H2OFrame to provide an RDD-like API. In this case, data is not duplicated but served directly from the underlying H2OFrame.

Converting from an RDD/ DataFrame to an H2OFrame requires data duplication because it transfers data from the RDD storage into H2OFrame. However,
data stored in an H2OFrame is heavily compressed and does not need to be preserved in RDD.

Figure 5: Sharing between Spark and H2O inside an executor JVM.

### 3.2 Provided Primitives

Sparkling Water provides several primitives (for more information, refer to Table 1). Before using H2O algorithms and data structures, the first step is to create and start the H2OContext instance using the val hc = new H2OContext(sc).start() call.

The H2OContext contains the necessary information for running H2O services and exposes methods for data transformation between the Spark RDD or DataFrame and the H2OFrame. Starting H2OContext involves a distributed operation that contacts all accessible Spark executor nodes and initializes H2O services (such as the key-value store and RPC) inside the executors’ JVMs.

When H2OContext is running, H2O data structures and algorithms can be manipulated. The key data structure is H2OFrame, which represents a distributed table composed of vectors. A new H2OFrame can be created using one of the following methods:

- loading a cluster local file (a file located on each node of the cluster):
• loading a file from HDFS/S3/S3N/S3A:

```scala
val h2oFrame = new H2OFrame(URI.create("hdfs://data/iris.csv"))
```

• loading multiple files from HDFS/S3/S3N/S3A:

```scala
val h2oFrame = new H2OFrame(URI.create("hdfs://data/iris/01.csv"), URI.create("hdfs://data/iris/02.csv"))
```

• transforming Spark RDD or DataFrame:

```scala
val h2oFrame = h2oContext.asH2OFrame(rdd)
```

• referencing existing H2OFrame by its key

```scala
val h2oFrame = new H2OFrame("iris.hex")
```
<table>
<thead>
<tr>

<td>H2O Algorithm</td>
<td>package hex</td>
<td>Represents the H2O machine learning algorithms library, including DeepLearning, GBM, GLM, DRF, and other algorithms.</td>
</tr>
</tbody>
</table>

Table 1: Sparkling Water primitives

When the H2OContext is running, any H2O algorithm can be called. Most of provided algorithms are located in the hex package. Calling an algorithm is composed of two steps:

- **Specifying parameters:**

  ```scala
  1 val train: H2OFrame = new H2OFrame(new File("prostate.csv"))
  2 val gbmParams = new GBMParameters()
  3 gbmParams._train = train
  4 gbmParams._response_column = 'CAPSULE
  5 gbmParams._ntrees = 10
  ```

- **Creating the model builder and launching computations.** The `trainModel` method is non-blocking and returns a job representing the computation.

  ```scala
  1 val gbmModel = new GBM(gbmParams).trainModel.get
  ```
4 Programming API

4.1 Starting H2O Services

```
val sc: SparkContext = ...
val hc = H2OContext.getOrCreate(sc)
```

or:

```
val sc: SparkContext = ...
val hc = new H2OContext(sc).start()
```

When the number of Spark nodes is known, it can be specified in the `getOrCreate` call:

```
val hc = H2OContext.getOrCreate(sc, numOfSparkNodes)
```

or, in start method of `H2OContext`:

```
val hc = new H2OContext(sc).start(numOfSparkNodes)
```

The former variant is preferred, because it initiates and starts `H2OContext` in one call and can be used to obtain already existing `H2OContext`. It is semantically the same as the latter variant though.

4.2 Memory Allocation

H2O resides in the same executor JVM as Spark. The memory provided for H2O is configured via Spark; refer to Spark configuration for more details.

Generic configuration

- Configure the Executor memory (i.e., memory available for H2O) via the Spark configuration property `spark.executor.memory`. For example, `bin/sparkling-shell --conf spark.executor.memory=5g` or configure the property in `$SPARK_HOME/conf/spark-defaults.conf`

- Configure the Driver memory (i.e., memory available for H2O client running inside the Spark driver) via the Spark configuration property `spark.driver.memory`. For example, `bin/sparkling-shell --conf spark.driver.memory=4g` or configure the property in `$SPARK_HOME/conf/spark-defaults.conf`. 
Yarn specific configuration

- Refer to the Spark documentation https://spark.apache.org/docs/latest/running-on-yarn.html
- For JVMs that require a large amount of memory, we strongly recommend configuring the maximum amount of memory available for individual mappers.

### 4.3 Converting H2OFrame into RDD[T]

The H2OContext class provides the explicit conversion, asRDD, which creates an RDD-like wrapper around the provided H2OFrame:

```scala
1 def asRDD[A <: Product: TypeTag: ClassTag](fr: H2OFrame): RDD[A]
```

The call expects the type A to create a correctly-typed RDD. The conversion requires type A to be bound by Product interface. The relationship between the columns of H2OFrame and the attributes of class A is based on name matching.

**Example**

```scala
1 val df: H2OFrame = ...
2 val rdd = asRDD[Weather](df)
```

### 4.4 Converting H2OFrame into DataFrame

The H2OContext class provides the explicit conversion, asDataFrame, which creates a DataFrame-like wrapper around the provided H2OFrame. Technically, it provides the RDD[sql.Row] RDD API:

```scala
1 def asDataFrame(fr: H2OFrame)(implicit sqlContext: SQLContext): DataFrame
```

This call does not require any type of parameters, but since it creates DataFrame instances, it requires access to an instance of SQLContext. In this case, the instance is provided as an implicit parameter of the call. The parameter can be passed in two ways: as an explicit parameter or by introducing an implicit variable into the current context.

The schema of the created instance of the DataFrame is derived from the column name and the types of H2OFrame specified.
Example

Using an explicit parameter in the call to pass `sqlContext`:

```scala
val sqlContext = new SQLContext(sc)
val schemaRDD = asDataFrame(h2oFrame)(sqlContext)
```

or as implicit variable provided by actual environment:

```scala
implicit val sqlContext = new SQLContext(sc)
val schemaRDD = asDataFrame(h2oFrame)
```

4.5 Converting RDD[T] into H2OFrame

The `H2OContext` provides implicit conversion from the specified `RDD[A]` to `H2OFrame`. As with conversion in the opposite direction, the type `A` has to satisfy the upper bound expressed by the type `Product`. The conversion will create a new `H2OFrame`, transfer data from the specified `RDD`, and save it to the H2O K/V data store.

```scala
implicit def asH2OFrame[A <: Product: TypeTag](rdd: RDD[A]): H2OFrame
```

The API also provides explicit version which allows for specifying name for resulting `H2OFrame`.

```scala
def asH2OFrame[A <: Product: TypeTag](rdd: RDD[A],
    frameName: String): H2OFrame
```

Example

```scala
val rdd: RDD[Weather] = ...
import h2oContext._
// Implicit call of H2OContext.asH2OFrame[Weather](rdd)
// is used
val hf: H2OFrame = rdd
// Explicit call of of H2OContext API with name for resulting H2OFrame
val hfNamed: H2OFrame = h2oContext.asH2OFrame(rdd, "hfNamed")
```
4.6 Converting DataFrame into H2OFrame

The H2OContext provides implicit conversion from the specified DataFrame to H2OFrame. The conversion will create a new H2OFrame, transfer data from the specified DataFrame, and save it to the H2O K/V data store.

```
implicit def asH2OFrame(rdd: DataFrame): H2OFrame
```

The API also provides explicit version which allows for specifying name for resulting H2OFrame.

```
def asH2OFrame(rdd: DataFrame, frameName: String): H2OFrame
```

Example

```
val df: DataFrame = ...
import h2oContext._
// Implicit call of H2OContext.asH2OFrame(srdd) is used
val hf: H2OFrame = df
// Explicit call of H2Context API with name for resulting H2OFrame
val hfNamed: H2OFrame = h2oContext.asH2OFrame(df, "hfNamed")
```

4.7 Creating H2OFrame from an Existing Key

If the H2O cluster already contains a loaded H2OFrame referenced by the key train.hex, it is possible to reference it from Sparkling Water by creating a proxy H2OFrame instance using the key as the input:

```
val trainHF = new H2OFrame("train.hex")
```

4.8 Type Map Between H2OFrame and Spark DataFrame Types

For all primitive Scala types or Spark SQL types (see org.apache.spark.sql.types) which can be part of Spark RDD/DataFrame, we provide mapping into H2O vector types (numeric, categorical, string, time, UUID - see water.fvec.Vec):
### Scala type | SQL type | H2O type
---|---|---
NA | BinaryType | Numeric
Byte | ByteType | Numeric
Short | ShortType | Numeric
Integer | IntegerType | Numeric
Long | LongType | Numeric
Float | FloatType | Numeric
Double | DoubleType | Numeric
String | StringType | String
Boolean | BooleanType | Numeric
java.sql.Timestamp | TimestampType | Time

### 4.9 Calling H2O Algorithms

1. Create the parameters object that holds references to input data and parameters specific for the algorithm:

   ```scala
   val train: RDD = ...
   val valid: H2OFrame = ...
   val gbmParams = new GBMParameters()
   gbmParams._train = train
   gbmParams._valid = valid
   gbmParams._response_column = 'bikes
   gbmParams._ntrees = 500
   gbmParams._max_depth = 6
   ```

2. Create a model builder:

   ```scala
   val gbm = new GBM(gbmParams)
   ```

3. Invoke the model build job and block until the end of computation (trainModel is an asynchronous call by default):

   ```scala
   val gbmModel = gbm.trainModel.get
   ```

### 4.10 Using Spark Data Sources with H2OFrame

Spark SQL provides configurable data source for SQL tables. Sparkling Water enable H2OFrame to be used as data source to load/save data from/to Spark SQL table.
4.10.1 Reading from H2OFrame

Let’s suppose we have a H2OFrame. The shortest way to load a DataFrame from H2OFrame with default settings is:

```scala
val df = sqlContext.read.h2o(frame.key)
```

There are two more ways to load a DataFrame from H2OFrame allowing us to specify additional options:

```scala
val df = sqlContext.read.format("h2o").option("key", frame.key.toString).load()
```

or

```scala
val df = sqlContext.read.format("h2o").load(frame.key.toString)
```

4.10.2 Saving to H2OFrame

Let’s suppose we have DataFrame df. The shortest way to save the DataFrame as H2OFrame with default settings is:

```scala
df.write.h2o("new_key")
```

There are two more ways to save the DataFrame as H2OFrame allowing us to specify additional options:

```scala
df.write.format("h2o").option("key", "new_key").save()
```

or

```scala
df.write.format("h2o").save("new_key")
```

All three variants save the DataFrame as H2OFrame with the key "new_key". They won’t succeed if a H2OFrame with the same key already exists.

4.10.3 Loading and Saving Options

If the key is specified as 'key' option, and also in the load/save method, the option 'key' is preferred:
In both examples, "key_one" is used.

### 4.10.4 Specifying Saving Mode

There are four save modes available when saving data using Data Source API—see http://spark.apache.org/docs/latest/sql-programming-guide.html#save-modes

- If "append" mode is used, an existing H2OFrame with the same key is deleted, and a new one created with the same key. The new frame contains the union of all rows from the original H2OFrame and the appended DataFrame.

- If "overwrite" mode is used, an existing H2OFrame with the same key is deleted, and new one with the new rows is created with the same key.

- If "error" mode is used, and a H2OFrame with the specified key already exists, an exception is thrown.

- If "ignore" mode is used, and a H2OFrame with the specified key already exists, no data are changed.
5 Deployment

Since Sparkling Water is designed as a regular Spark application, its deployment cycle is strictly driven by Spark deployment strategies (refer to Spark documentation\(^3\)). Spark applications are deployed by the `spark-submit` \(^4\) script that handles all deployment scenarios:

```
./bin/spark-submit \ 
  --class <main-class> \ 
  --master <master-url> \ 
  --conf <key>=<value> \ 
  ... # other options \ 
  <application-jar> [application-arguments]
```

- `--class`: Name of main class with `main` method to be executed. For example, the `water.SparklingWaterDriver` application launches H2O services.
- `--master`: Location of Spark cluster
- `--conf`: Specifies any configuration property using the format `key=value`
- `application-jar`: Jar file with all classes and dependencies required for application execution
- `application-arguments`: Arguments passed to the main method of the class via the `--class` option

5.1 Referencing Sparkling Water

5.1.1 Using Fatjar

The Sparkling Water archive provided at `http://h2o.ai/download` contains a Fatjar with all classes required for Sparkling Water run.

An application submission with Sparkling Water Fatjar is using the `--jars` option which references included fatjar.

\(^3\)Spark deployment guide `http://spark.apache.org/docs/latest/cluster-overview.html`
\(^4\)Submitting Spark applications `http://spark.apache.org/docs/latest/submitting-applications.html`
5.1.2 Using Spark Package

Sparkling Water is also published as a Spark package. The benefit of using the package is that you can use it directly from your Spark distribution without need to download Sparkling Water.

For example, if you have Spark version 1.6 and would like to use Sparkling Water version 1.6.1 and launch example CraigslistJobTitlesStreamingApp, then you can use the following command:

```
$SPARK_HOME/bin/spark-submit \
--packages ai.h2o:sparkling-water-core_2.10:1.6.1,ai.h2o:sparkling-water-examples_2.10:1.6.1 \
--class org.apache.spark.examples.h2o.CraigslistJobTitlesStreamingApp \
/dev/null
```

The Spark option `--packages` points to coordinate of published Sparkling Water package in Maven repository.

The similar command works for spark-shell:

```
$SPARK_HOME/bin/spark-shell \
--packages ai.h2o:sparkling-water-core_2.10:1.6.1,ai.h2o:sparkling-water-examples_2.10:1.6.1
```

The same command works for Python programs:

```
$SPARK_HOME/bin/spark-submit \
--packages ai.h2o:sparkling-water-core_2.10:1.6.1,ai.h2o:sparkling-water-examples_2.10:1.6.1\nexample.py
```

Note: When you are using Spark packages you do not need to download Sparkling Water distribution! Spark installation is sufficient!
5.2 Target Deployment Environments

Sparkling Water supports deployments to the following Spark cluster types:

- Local cluster
- Standalone cluster
- YARN cluster

5.2.1 Local cluster

The local cluster is identified by the following master URLs - local, local[K], or local[*]. In this case, the cluster is composed of a single JVM and is created during application submission.

For example, the following command will run the ChicagoCrimeApp application inside a single JVM with a heap size of 5g:

```
$SPARK_HOME/bin/spark-submit \
--conf spark.executor.memory=5g \
--conf spark.driver.memory=5g \
--master local[*] \
--packages ai.h2o:sparkling-water-examples_2.10:1.6.1 \
--class org.apache.spark.examples.h2o.ChicagoCrimeApp \
/dev/null
```

5.2.2 On Standalone Cluster

For AWS deployments or local private clusters, the standalone cluster deployment is typical. Additionally, a Spark standalone cluster is also provided by Hadoop distributions like CDH or HDP. The cluster is identified by the URL spark://IP:PORT.

The following command deploys the ChicagoCrimeApp on a standalone cluster where the master node is exposed on IP machine-foo.bar.com and port 7077:

---

5Refer to Spark documentation [http://spark.apache.org/docs/latest/spark-standalone.html](http://spark.apache.org/docs/latest/spark-standalone.html)
$SPARK_HOME/bin/spark-submit \ 
  --conf spark.executor.memory=5g \ 
  --conf spark.driver.memory=5g \ 
  --master spark://machine-foo.bar.com:7077 \ 
  --packages ai.h2o:sparkling-water-examples_2 \ 
  .10:1.6.1 \ 
  --class org.apache.spark.examples.h2o.\ 
    ChicagoCrimeApp \ 
  /dev/null

In this case, the standalone Spark cluster must be configured to provide the requested 5g of memory per executor node.

### 5.2.3 On YARN Cluster

Because it provides effective resource management and control, most production environments use YARN for cluster deployment. In this case, the environment must contain the shell variable HADOOP_CONF_DIR or YARN_CONF_DIR which point to Hadoop configuration directory (e.g., /etc/hadoop/conf).

$SPARK_HOME/bin/spark-submit \ 
  --conf spark.executor.memory=5g \ 
  --conf spark.driver.memory=5g \ 
  --num-executors 5 \ 
  --master yarn-client \ 
  --packages ai.h2o:sparkling-water-examples_2 \ 
  .10:1.6.1 \ 
  --class org.apache.spark.examples.h2o.\ 
    ChicagoCrimeApp \ 
  /dev/null

The command in the example above creates a YARN job and requests for 5 nodes, each with 5G of memory. The yarn-client option forces driver to run in the client process.

---

## 5.3 Sparkling Water Configuration Properties

The following configuration properties can be passed to Spark to configure Sparkling Water:

### Generic parameters

<table>

Building a Standalone Application

Sparkling Water Example Project
This is a simple example project to start coding with Sparkling Water.

Dependencies
This droplet uses Sparkling Water 1.6 which integrates:
- Spark 1.6
- H2O 3.8 Tukey

For more details see build.gradle.

Project structure

```
grade/ ........ Gradle definition files
src/ ........... Source code
  main/ ....... Main implementation code
  scala/
  test/ ....... Test code
  scala/
build.gradle ... Build file for this project
gradlew ........ Gradle wrapper
```

Project building
For building, please, use provided gradlew command:

```
./gradlew build
```

Run demo
For running a simple application:

```
./gradlew run
```

Starting with IDEA
There are two ways to open this project in IntelliJ IDEA
Using Gradle build file directly:

Open the project’s `build.gradle` in IDEA via File → Open

or using Gradle generated project files:

1. Generate Idea configuration files via `./gradlew idea`
2. Open project in Idea via File → Open

Note: To clean up Idea project files please launch `./gradlew cleanIdea`

Starting with Eclipse

1. Generate Eclipse project files via `./gradlew eclipse`
2. Open project in Eclipse via File → Import → Existing Projects into Workspace

Running tests

To run tests, please, run:

```bash
./gradlew test
```

Checking code style

To check codestyle:

```bash
./gradlew scalaStyle
```

Creating and Running Spark Application

Create application assembly which can be directly submitted to Spark cluster:

```bash
./gradlew shadowJar
```

The command creates jar file `build/libs/sparkling-water-droplet-app.jar` containing all necessary classes to run application on top of Spark cluster.

Submit application to Spark cluster (in this case, local cluster is used):

```bash
export MASTER='local-cluster[3,2,1024]'
$SPARK_HOME/bin/spark-submit --class water.droplets.SparklingWaterDroplet build/libs/sparkling-water-droplet-all.jar
```
What is PySparkling Water?

PySparkling Water is an integration of Python with Sparkling water. It allows the user to start H2O services on a spark cluster from Python API.

In the PySparkling Water driver program, the SparkContext (sc) uses Py4J to start the driver JVM and the JAVA SparkContext is used to create H2OContext (hc). This in turn starts the H2O cloud in the Spark ecosystem. Once the H2O cluster is up, H2O-Python package is used to interact with the cloud and run H2O algorithms. All pure H2O calls are executed via H2O's REST API interface. Users can easily integrate their regular PySpark workflow with H2O algorithms using PySparkling Water.

PySparkling Water programs can be launched as an application, or in an interactive shell, or notebook environment.

7.1 Getting Started:

1. Download Spark (if not already installed) from the Spark Downloads Page.
   Choose Spark release : 1.6.0
   Choose a package type: Pre-built for Hadoop 2.4 and later

2. Point SPARK_HOME to the existing installation of Spark and export variable MASTER.

   ```
   export SPARK_HOME="/path/to/spark/installation"
   ```

   Launch a local Spark cluster with 3 worker nodes with 2 cores and 1g per node.

   ```
   export MASTER="local-cluster[3,2,1024]"
   ```

3. From your terminal, run:

   ```
   cd ~/Downloads
   unzip sparkling-water-1.6.1.zip
   cd sparkling-water-1.6.1
   ```

   Start an interactive Python terminal:

   ```
   bin/pysparkling
   ```
What is PySparkling Water?

Or start a notebook:

```
IPYTHON_OPTS="notebook" bin/pysparkling
```

4. Create an H2O cloud inside the Spark cluster and import H2O-Python package:

```
from pysparkling import *
hc = H2OContext(sc).start()
import h2o
```

Alternatively, to launch on YARN:

```
wget http://h2o-release.s3.amazonaws.com/sparkling-water/rel-1.6/1/sparkling-water-1.6.1.zip
unzip sparkling-water-1.6.1.zip
export SPARK_HOME="/path/to/spark/installation"
export HADOOP_CONF_DIR=/etc/hadoop/conf
export SPARKLING_HOME="/path/to/SparklingWater/installation"
$SPARKLING_HOME/bin/pysparkling --num-executors 3 --executor-memory 20g --executor-cores 10 --driver-memory 20g --master yarn-client
```

Then create an H2O cloud inside the Spark cluster and import H2O-Python package:

```
from pysparkling import *
hc = H2OContext(sc).start()
import h2o
```

Or to launch as a Spark Package application:

```
$SPARK_HOME/bin/spark-submit --packages ai.h2o:sparkling-water-core_2.10:1.6.1 --py-files
$SPARKLING_HOME/py/dist/pySparkling-1.6.1-py2.7.egg
$SPARKLING_HOME/py/examples/scripts/H2OContextDemo.py
```
7.2 Using Spark Data Sources

The way that a H2OFrame can be used as Spark’s data source differs a little bit in Python from Scala.

7.2.1 Reading from H2OFrame

Let’s suppose we have an H2OFrame. There are two ways how the DataFrame can be loaded from H2OFrame in pySparkling:

```python
1 df = sqlContext.read.format("h2o").option("key", frame.frame_id).load()
```

or

```python
1 df = sqlContext.read.format("h2o").load(frame.frame_id)
```

7.2.2 Saving to H2OFrame

Let’s suppose we have a DataFrame df. There are two ways how DataFrame can be saved as H2OFrame in pySparkling:

```python
1 df.write.format("h2o").option("key", "new_key").save()
```

or

```python
1 df.write.format("h2o").save("new_key")
```

Both variants save DataFrame as a H2OFrame with key new_key. They won’t succeed if a H2OFrame with the same key already exists.

7.2.3 Loading and Saving Options

If the key is specified as 'key' option, and also in the load/save method, the option 'key' is preferred:

```python
1 df = sqlContext.read.from("h2o").option("key", "key_one").load("key_two")
```
or

```python
def = sqlContext.read.from("h2o").option("key","key_one ").save("key_two")
```

In both examples, *key_one* is used.
8 A Use Case Example

8.1 Predicting Arrival Delay in Minutes - Regression

What is the task?

As Chief Air Traffic Controller, your job is come up with a prediction engine that can be used to tell passengers whether an incoming flight will be delayed by X number of minutes. To accomplish this task, we have an airlines dataset containing ~44k flights since 1987 with features such as: Origin and Destination codes, distance traveled, carrier, etc. The key variable we are trying to predict is 'ArrDelay' (arrival delay) in minutes. We will do this leveraging H2O and the Spark SQL library.

Spark SQL

One of the many cool features about the Spark project is the ability to initiate a SQL context within our application that enables us to write SQL-like queries against an existing DataFrame. Given the ubiquitous nature of SQL, this is very appealing to data scientists who may not be comfortable yet with Scala / Java / Python, but want to perform complex manipulations of their data.

Within the context of this example, we are going to first read in the airlines dataset and then process a weather file which contains the weather data at the arriving city. Joining the two tables will require a SQL context such that we can write an INNER JOIN against the two independent DataFrames. Let’s get started!

Data Ingest

Our first order of business is to process both files, the flight data and the weather data:

```scala
object AirlinesWithWeatherDemo extends SparkContextSupport {
  def main(args: Array[String]): Unit = {
    // Configure this application
    val conf: SparkConf = configure("Sparkling Water: Join of Airlines with Weather Data")
    // Create SparkContext to execute application on Spark cluster
    val sc = new SparkContext(conf)
```
The flight data file is imported directly into H2O already as an H2OFrame. The weather table, however, is first processed in Spark where we do some parsing of the data and data scrubbing.

After both files have been processed, we then take the airlines data that currently sits in H2O and it pass back into Spark whereby we filter for those flights ONLY arriving at Chicago’s O’Hare International Airport:

At this point, we are ready to join these two tables which are currently Spark RDDs. The workflow required for this is as follows:

- Convert the RDD into a DataFrame and register the resulting DataFrame as 'TempTable'
A Use Case Example

val sqlContext = new SQLContext(sc)
// Import implicit conversions
import sqlContext.implicits._
flightsToORD.toDF.registerTempTable("FlightsToORD")
weatherTable.toDF.registerTempTable("WeatherORD")

- Join the two temp tables using Spark SQL

val bigTable = sqlContext.sql("SELECT f.Year,f.Month,f.DayofMonth,
|f.CRSDepTime,f.CRSArrTime,f.CRSElapsedTime,
|f.UniqueCarrier,f.FlightNum,f.TailNum,
|f.Origin,f.Distance,
|w.TmaxF,w.TminF,w.TmeanF,w.PrcpIn,w.SnowIn,w .CDD,w.HDD,w.GDD,
|f.ArrDelay
|FROM FlightsToORD f
|JOIN WeatherORD w
|ON f.Year=w.Year AND f.Month=w.Month AND f.
|DayofMonth=w.Day
|WHERE f.ArrDelay IS NOT NULL""".stripMargin)

- Transfer the joined table from Spark back to H2O to run an algorithm against

val train: H2OFrame = bigTable

**H2O Deep Learning**

Now we have our dataset loaded into H2O. Recall this dataset has been filtered to only include the flights and weather data on Chicago Ohare. It’s now time to run a machine learning algorithm to predict flight delay in minutes. As always, we start off with the necessary imports we need followed by declaring the parameters that we wish to control:
A Use Case Example

val dlParams = new DeepLearningParameters()
dlParams._train = train
dlParams._response_column = 'ArrDelay
dlParams._epochs = 5
dlParams._activation = Activation.RectifierWithDropout
dlParams._hidden = Array[Int](100, 100)

val dl = new DeepLearning(dlParams)
val dlModel = dl.trainModel.get

More parameters for Deep Learning and all other algorithms can be found in H2O documentation at http://docs.h2o.ai.

Now we can run this model on our test dataset to score the model against our holdout dataset:

val predictionH2OFrame = dlModel.score(bigTable)('
predict)
val predictionsFromModel = asRDD[DoubleHolder](
  predictionH2OFrame).collect.map(_.result.getOrElse
  (Double.NaN))
println(predictionsFromModel.mkString("\n=== Model predictions: ", ", ", ", ", ...
"))

The full source for the application is here: http://bit.ly/1mo3XO2
FAQ

Where do I find the Spark logs?
Spark logs are located in the directory `$SPARK_HOME/work/app-<AppName>` (where `<AppName>` is the name of your application).

Spark is very slow during initialization, or H2O does not form a cluster. What should I do?
Configure the Spark variable `SPARK_LOCAL_IP`. For example:

```
export SPARK_LOCAL_IP='127.0.0.1'
```

How do I increase the amount of memory assigned to the Spark executors in Sparkling Shell?
Sparkling Shell accepts common Spark Shell arguments. For example, to increase the amount of memory allocated by each executor, use the `spark.executor.memory` parameter:

```
bin/sparkling-shell --conf "spark.executor.memory=4g"
```

How do I change the base port H2O uses to find available ports?
The H2O accepts `spark.ext.h2o.port.base` parameter via Spark configuration properties:

```
bin/sparkling-shell --conf "spark.ext.h2o.port.base=13431"
```
For a complete list of configuration options, refer to Devel Documentation.

How do I use Sparkling Shell to launch a Scala test.script that I created?
Sparkling Shell accepts common Spark Shell arguments. To pass your script, please use `-i` option of Spark Shell:

```
bin/sparkling-shell -i test.script
```

How do I increase PermGen size for Spark driver?
Specify `--conf spark.driver.extraJavaOptions="-XX:MaxPermSize=384m"`

How do I add Apache Spark classes to Python path?
Configure the Python path variable `PYTHONPATH`:

```
export PYTHONPATH=$SPARK_HOME/python:$SPARK_HOME/python/build:$PYTHONPATH
```
```
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-0.8.2.1-src.zip:$PYTHONPATH
```
Trying to import a class from the hex package in Sparkling Shell but getting weird error:

```java
error: missing arguments for method hex in object functions; follow this method with '_' if you want to treat it as a partially applied
```

In this case you are probably using Spark 1.5 which is importing SQL functions into Spark Shell environment. Please use the following syntax to import a class from the hex package:

```java
import _root_.hex.tree.gbm.GBM
```
